# **Unit 6: Introduction to linear regression**

1. Introduction to regression

Sta 101 - Spring 2016

Duke University, Department of Statistical Science

Dr. Çetinkaya-Rundel

Slides posted at http://bit.ly/sta101\_s16

## Modeling numerical variables

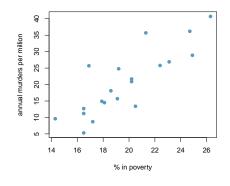

- ➤ So far we have worked with single numerical and categorical variables, and explored relationships between numerical and categorical, and two categorical variables.
- ▶ In this unit we will learn to quantify the relationship between two numerical variables, as well as modeling numerical response variables using a numerical or categorical explanatory variable.
- ▶ In the next unit we'll learn to model numerical variables using many explanatory variables at once.

# Guessing the correlation

#### Clicker question

Which of the following is the best guess for the correlation between annual murders per million and percentage living in poverty?

- (a) -1.52
- **(b)** -0.63
- (c) -0.12
- (d) 0.02
- (e) 0.84

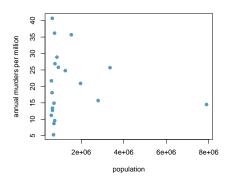

2

## Clicker question

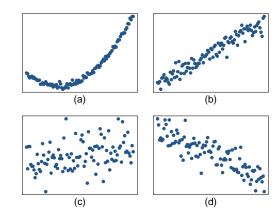

Which of the following is the best guess for the correlation between annual murders per million and population size?

- (a) -0.97
- **(b)** -0.61
- **(c)** -0.06
- **(d)** 0.55
- **(e)** 0.97

### Clicker question

Which of the following is has the strongest correlation, i.e. correlation coefficient closest to +1 or -1?

4

Play the game!

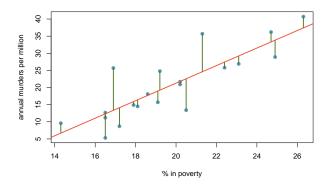

Spurious correlations

5

Upload a screen shot to Sakai (EC - Correlation Game) by midnight on April 8 for extra credit PS 6 (1 pt on the problem set). http://guessthecorrelation.com/

Remember: correlation does not always imply causation! http://www.tylervigen.com/ ▶ Residuals are the leftovers from the model fit, and calculated as the difference between the observed and predicted y:  $e_i = y_i - \hat{y}_i$ 

- ▶ The least squares line minimizes squared residuals:
  - Population data:  $\hat{y} = \beta_0 + \beta_1 x$
  - Sample data:  $\hat{y} = b_0 + b_1 x$

► *Slope:* For each <u>unit</u> increase in <u>x</u>, <u>y</u> is expected to behigher/lower on average by the slope.

$$b_1 = \frac{s_y}{s_x} R$$

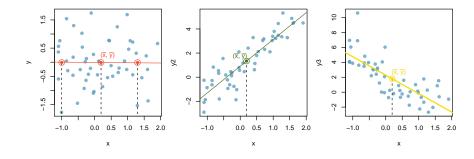

▶ *Intercept:* When  $\underline{x} = 0$ , y is expected to equal the intercept.

$$b_0 = \bar{y} - b_1 \bar{x}$$

- The calculation of the intercept uses the fact the a regression line **always** passes through  $(\bar{x}, \bar{y})$ .

Why does the regression line **always** pass through  $(\bar{x}, \bar{y})$ ?

- ▶ If there is no relationship between x and y ( $b_1 = 0$ ), the best guess for  $\hat{y}$  for any value of x is  $\bar{y}$ .
- ▶ Even when there is a relationship between x and y ( $b_1 \neq 0$ ), the best guess for  $\hat{y}$  when  $x = \bar{x}$  is still  $\bar{y}$ .

Application exercise: 6.1 Linear model

See course website for details

#### Clicker question

# What is the interpretation of the slope?

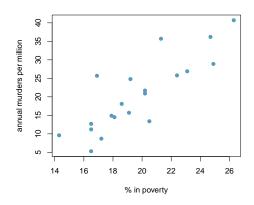

- (a) Each additional percentage in those living in poverty increases number of annual murders per million by 2.56.
- (b) For each percentage increase in those living in poverty, the number of annual murders per million is expected to be higher by 2.56 on average.
- (c) For each percentage increase in those living in poverty, the number of annual murders per million is expected to be lower by 29.91 on average.
- (d) For each percentage increase annual murders per million, the percentage of those living in poverty is expected to be higher by 2.56 on average.

#### Clicker question

Suppose you want to predict annual murder count (per million) for a series of districts that were not included in the dataset. For which of the following districts would you be most comfortable with your prediction?

A district where % in poverty =

- (a) 5%
- (b) 15%
- (c) 20%
- (d) 26%
- (e) 40%

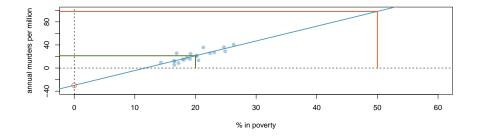

12

13

15

# A note about the intercept

Sometimes the intercept might be an extrapolation: useful for adjusting the height of the line, but meaningless in the context of the data.

## Calculating predicted values

```
By hand: \widehat{\text{murder}} = -29.91 + 2.56 poverty
```

The predicted number of murders per million per year for a county with 20% poverty rate is:

$$\widehat{\text{murder}} = -29.91 + 2.56 \times 20 = 21.29$$

#### In R:

```
# load data
murder <- read.csv("https://stat.duke.edu/~mc301/data/murder.csv")
# fit model
m_mur_pov <- lm(annual_murders_per_mil ~ perc_pov, data = murder)
# create new data
newdata <- data.frame(perc_pov = 20)
# predict
predict(m_mur_pov, newdata)</pre>
```

```
1
21.28663
```

14

# Summary of main ideas

- 1. Correlation coefficient describes the strength and direction of the linear association between two numerical variables
- 2. Least squares line minimizes squared residuals
- 3. Interpreting the least squares line
- 4. Predict, but don't extrapolate
