# **Unit 2: Probability and distributions**

# 2. Bayes' theorem and Bayesian inference

Sta 101 - Spring 2016

Duke University, Department of Statistical Science

#### 2. Main ideas

- Probability trees are useful for conditional probability calculations
- 2. Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- Posterior probability and p-value do not mean the same thing

#### Announcements

- ▶ If you received an email from me about your clicker registration being missing and you still have not given me your info on the Google doc, please do that ASAP!
- ▶ PS 2 is posted
- Start reviewing Unit 3 materials

#### 2. Main ideas

- 2. Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- 3. Posterior probability and p-value do not mean the same thing

### 2. Main ideas

- 1. Probability trees are useful for conditional probability calculations
- 2. Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- Posterior probability and p-value do not mean the same thing

## 1. Probability trees are useful for conditional probability calculations

- Probability trees are useful for organizing information in conditional probability calculations
- ► They're especially useful in cases where you know P(A | B), along with some other information, and you're asked for P(B | A)

### 2. Main ideas

- Probability trees are useful for conditional probability calculations
- 2. Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- 3. Posterior probability and p-value do not mean the same thing

▶ In Bayesian inference, probabilities are at times interpreted as degrees of belief.

- ▶ In Bayesian inference, probabilities are at times interpreted as degrees of belief.
- ➤ You start with a set of **prior beliefs** (or prior probabilities).

- ▶ In Bayesian inference, probabilities are at times interpreted as degrees of belief.
- ➤ You start with a set of **prior beliefs** (or prior probabilities).
- You observe some data.

- ▶ In Bayesian inference, probabilities are at times interpreted as degrees of belief.
- ➤ You start with a set of **prior beliefs** (or prior probabilities).
- You observe some data.
- ▶ Based on that data, you update your beliefs.

- ▶ In Bayesian inference, probabilities are at times interpreted as degrees of belief.
- ➤ You start with a set of **prior beliefs** (or prior probabilities).
- You observe some data.
- Based on that data, you update your beliefs.
- These new beliefs are called posterior beliefs (or posterior probabilities), because they are post-data.

- ▶ In Bayesian inference, probabilities are at times interpreted as degrees of belief.
- ➤ You start with a set of **prior beliefs** (or prior probabilities).
- You observe some data.
- Based on that data, you update your beliefs.
- These new beliefs are called posterior beliefs (or posterior probabilities), because they are post-data.
- You can iterate this process.

### Dice game

- ▶ Two dice: 6-sided and 12-sided
  - I keep one die on the left and one die on the right

## Dice game

- ▶ Two dice: 6-sided and 12-sided
  - I keep one die on the left and one die on the right
- ▶ The "good die" is the 12-sided die.

- ▶ Two dice: 6-sided and 12-sided
  - I keep one die on the left and one die on the right
- ► The "good die" is the 12-sided die.
- ▶ Ultimate goal: come to a class consensus about whether the die on the left or the die on the right is the "good die"

- ▶ Two dice: 6-sided and 12-sided
  - I keep one die on the left and one die on the right
- ► The "good die" is the 12-sided die.
- Ultimate goal: come to a class consensus about whether the die on the left or the die on the right is the "good die"
- We will start with priors, collect data, and calculate posteriors, and make a decision or iterate until we're ready to make a decision

### Prior probabilities

- ▶ At each roll I tell you whether you won or not (win =  $\geq 4$ )
  - P(win | 6-sided die) =  $0.5 \rightarrow$  bad die
  - P(win | 12-sided die) =  $0.75 \rightarrow \text{good die}$

### Prior probabilities

- ▶ At each roll I tell you whether you won or not (win =  $\geq 4$ )
  - P(win | 6-sided die) =  $0.5 \rightarrow$  bad die
  - P(win | 12-sided die) = 0.75 → good die
- The two competing claims are

 $H_1$ : Good die is on left

 $H_2$ : Good die is on right

- ▶ At each roll I tell you whether you won or not (win =  $\geq 4$ )
  - P(win | 6-sided die) =  $0.5 \rightarrow$  bad die
  - P(win | 12-sided die) =  $0.75 \rightarrow \text{good die}$
- The two competing claims are

 $H_1$ : Good die is on left

 $H_2$ : Good die is on right

 Since initially you have no idea which is true, you can assign equal prior probabilities to the hypotheses

 $P(H_1 \text{ is true}) = 0.5$ 

 $P(H_2 \text{ is true}) = 0.5$ 

- ➤ You won't know which die I'm holding in which hand, left (L) or right (R). left = YOUR left
- You pick die (L or R), I roll it, and I tell you if you win or not, where winning is getting a number ≥ 4. If you win, you get a piece of candy. If you lose, I get to keep the candy.
- ▶ We'll play this multiple times with different contestants.
- ▶ I will not swap the sides the dice are on at any point.
- You get to pick how long you want play, but there are costs associated with playing longer.

	Truth	
Decision	L good, R bad	L bad, R good
Pick L	You get candy!	You lose all the candy :(
Pick R	You lose all the candy :(	You get candy!

## Sampling isn't free!

At each trial you risk losing pieces of candy if you lose (the die comes up < 4). Too many trials means you won't have much candy left. And if we spend too much class time and we may not get through all the material.

# Data and decision making

	Choice (L or R)	Result (win or loss)
Roll 1		
Roll 2		
Roll 3		
Roll 4		
Roll 5		
Roll 6		
Roll 7		

What is your decision? How did you make this decision?

## Posterior probability

➤ Posterior probability is the probability of the hypothesis given the observed data: P(hypothesis | data)

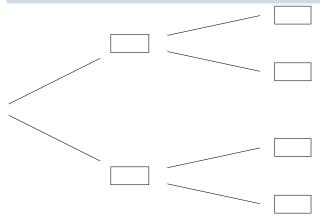

- ► Posterior probability is the probability of the hypothesis given the observed data: P(hypothesis | data)
- Using Bayes' theorem

$$P(hypothesis \mid data) = \frac{P(hypothesis \ and \ data)}{P(data)}$$

- ➤ Posterior probability is the probability of the hypothesis given the observed data: P(hypothesis | data)
- Using Bayes' theorem

$$P(hypothesis \mid data) = \frac{P(hypothesis \ and \ data)}{P(data)}$$
$$= \frac{P(data \mid hypothesis) \times P(hypothesis)}{P(data)}$$

Calculate the posterior probability for the hypothesis chosen in the first roll, and discuss how this might influence your decision for the next roll.

### 2. Main ideas

- Probability trees are useful for conditional probability calculations
- Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- 3. Posterior probability and p-value do not mean the same thing

## 3. Posterior probability and p-value do not mean the same thing

- p-value : P(observed or more extreme outcome | null hypothesis is true)
  - This is more like P(data | hyp) than P(hyp | data).
- posterior : P(hypothesis | data)
- Bayesian approach avoids the counter-intuitive Frequentist p-value for decision making, and more advanced Bayesian techniques offer flexibility not present in Frequentist models
- ▶ Watch out!
  - Bayes: A good prior helps, a bad prior hurts, but the prior matters less the more data you have.
  - p-value: It is really easy to mess up p-values: Goodman, 2008

## Application exercise: 2.2 Bayesian inference for drug testing

See the course website for instructions.

#### 2. Main ideas

- Probability trees are useful for conditional probability calculations
- 2. Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- Posterior probability and p-value do not mean the same thing

## Summary of main ideas

- 1. Probability trees are useful for conditional probability calculations
- 2. Bayesian inference: start with a prior, collect data, calculate posterior, make a decision or iterate
- 3. Posterior probability and p-value do not mean the same thing
